Integration brief

Verified payment reputation for AI agents

A seller's score only changes when the buyer's own wallet signs the update, so a seller cannot inflate its own record. This brief shows how an agent platform can check that record before it signs a payment.

Solana devnet. Independent project: not a product of any agent platform, and no partnership is implied. Last updated 5 November 2026.

What we are asking for

1. An activation token, so we can deploy a read-only App to Aomi Build (`aomi-build connect` requires one).
2. Whether App tools may make outbound HTTPS calls, and the tool timeout. Our reputation API can take up to about 50 seconds to answer when its free-tier host is asleep.
3. Whether an App can read Solana devnet data.

The problem

An agent that pays another agent has no way to tell a seller with a real track record from one that paid itself. A high score built from a single wallet looks the same as one built from many independent buyers.

What a platform gets

Reputation lookup
Read-only. Score, tier, confidence and vetting checks for any seller. No signing, no wallet access.

Policy gate
A `proceed` or `do_not_pay` recommendation under a Standard or Strict policy, with plain-language reasons.

Buyer-signed record
After payment the buyer's wallet signs the reputation update, in the same transaction as the payment.

The two tools

Tool	Returns
`check_agent_reputation(seller, policy?)`	Score, tier, confidence, vetting checks, recommendation and block reasons.
`list_top_agents(limit?)`	Sellers ranked by reputation, with tier and confidence.

Standard policy: reputation 80 or more, and buyer independence must not fail. Strict adds confidence of Medium or higher.

What exists today

- **Live demo** of the full flow: routex402.xyz/demo.html. The lookup and policy use live data, the simulation step is mocked, and the final step is a real devnet payment to a demo seller.
- **Read-only Aomi App**, written in Rust against aomi-sdk 7.0.0. It compiles and its unit tests pass. It is not deployed yet: github.com/msurfx/routex402-aomi-app.
- **On-chain proof.** One settled demo payment, where payment, protocol fee and reputation update are a single transaction signed by the buyer: view on Solscan. Program: 6pp5jD...P62vjt.
- **Explorer** with a vetting page per agent: routex402.xyz.

How it fits in an execution flow

1. The agent states its intent to pay a seller.
2. It calls `check_agent_reputation`.
3. A policy decides whether to continue. In the demo, our own top-scoring agent is blocked: every one of its payments came from a single buyer.
4. The platform simulates and the user approves, as it does today.
5. The buyer signs the payment and the reputation update together.

Limits you should know about

- Devnet only, with a small number of demo agents. Scores are evidence, not a guarantee.
- For some agents the distinct buyer count was not recorded, so confidence shows Unknown.
- The contract has not had an external audit. Mainnet is planned only after one.
- The tool shapes are a proposal, not a published API.

What comes next

- A versioned public API with server-side pagination.
- An unsigned-transaction endpoint so a platform can build the payment itself.
- Open seller registration.
- Contract hardening and an external audit, then mainnet.
